

## EXTERMINATORS

# BEE ELMINATION SERVICE

Although honey bees are beneficial in many ways, they can also be very dangerous and harmful depending on where they decide to nest.

### Colonization

When dealing with bees in buildings and homes, many times wall voids are chosen for colony sites. The bees may nest in the wall or attic some distance from where they enter. Colonies established in these locations can be a serious problem. It is best to remove or eliminate bees nested too close to human activity as soon as possible. The longer you delay, the more difficult removing them can become.

### Removal

Do not attempt to remove or eliminate bees without the proper protection equipment. Technicians at Gold Star Exterminators will provide trained, experienced, professional technicians to locate and safely eliminate bees.

### After Your Treatment

After the treatment is performed and most bees have been eliminated, there are still foraging bees that will later come into contact with the treated area upon returning to the hive. These bees will also be eliminated after being exposed.

### Prevent Re-Infestation

To prevent re-infestation of the area by another colony, it is recommended that the remaining nest be removed and discarded. After the colony is removed, plug all entrances through which other bee swarms might try to enter. Failure to remove a nest can lead to future problems with odor, attracting other pests, and future colonies. **Large bee colonies may have to be treated more than once before they are eliminated.** Immature bees at the comb at the time of treatment may emerge for up to 10 days after.
